

1. A method in a data processing system for testing hardware in a data processing system having multiple partitions, the method comprising:

- initializing a monitor process in a first partition assigned to a first processor; and
- initializing a random code generation process in a second partition associated with a second processor, wherein the random code generation process generates instructions and executes the instructions to test the second processor and wherein the monitor process monitors the random code generation process and resets the second processors if the random code generation process fails.

- 15 2. The method of claim 1, wherein the random code
generation process generates a heartbeat used by the
monitor process to determine whether the random code
generation process has failed.
3. The method of claim 2, wherein the random code
20 generation process calls a function to store data for the
heartbeat in a data structure.
4. The method of claim 3, wherein the monitor process
monitors the random code generation process by checking
the data structure.
- 25 5. The method of claim 1, wherein the first processor
and the second processor are located in a single chip.

Docket No.AUS920010672US1

6. The method of claim 1 further comprising:
responsive to detecting an error executing the
instructions in the second partition, preventing
termination of the second partition.

5 7. A data processing system comprising:
a bus system;
a communications unit connected to the bus system;
a memory connected to the bus system, wherein the
memory includes a set of instructions; and
10 a processing unit connected to the bus system,
wherein the processing unit executes the set of
instructions to initialize a monitor process in a first
partition assigned to a first processor and initialize a
random code generation process in a second partition
15 associated with a second processor in which the random
code generation process generates instructions and
executes the instructions to test the second processor
and in which the monitor process monitors the random code
generation process and resets the second processors if
20 the random code generation process fails.

8. A data processing system for testing hardware in a
data processing system has multiple partitions, the data
processing system comprising:
first initializing means for initializing a monitor
25 process in a first partition assigned to a first
processor; and
second initializing means for initializing a random
code generation process in a second partition associated
with a second processor, wherein the random code
30 generation process generates instructions and executes

00995000-092010672US1

Docket No.AUS920010672US1

the instructions to test the second processor and wherein the monitor process monitors the random code generation process and resets the second processors if the random code generation process fails.

5 9. The data processing system of claim 8, wherein the random code generation process generates a heartbeat used by the monitor process to determine whether the random code generation process has failed.

10 10. The data processing system of claim 9, wherein the random code generation process calls a function to store data for the heartbeat in a data structure.

11. The data processing system of claim 10, wherein the monitor process monitors the random code generation process by checking the data structure.

15 12. The data processing system of claim 8, wherein the first processor and the second processor are located in a single chip.

13. The data processing system of claim 8 further comprising:

20 preventing means, responsive to detecting an error executing the instructions in the second partition, for preventing termination of the second partition.

25 14. A computer program product in a computer readable medium for testing hardware in a data processing system having multiple partitions, the computer program product comprising:

T0260-0059560

Docket No.AUS920010672US1

first instructions for initializing a monitor process in a first partition assigned to a first processor; and

- second instructions for initializing a random code
- 5 generation process in a second partition associated with a second processor, wherein the random code generation process generates instructions and executes the instructions to test the second processor and wherein the monitor process monitors the random code generation
- 10 process and resets the second processors if the random code generation process fails.
